When Does Knowledge Distillation Hurt? Reliability-Aware Distillation for Low-Resource Language Summarization

[arxiv]

Dipto Sumit, Ankan Kumar Roy Srizon, Sadia Khair Rodela, Atia Haque Asha, Mourchona Afrin, Niloy Farhan, Farig Sadeque

! Summary may contain inaccuracies: The summary claims CHAD and EWAD+CPDP “both revolve around the same mechanism” / “decide when the teacher signal is reliable, and reduce its influence when it is not.” This accurately describes CHAD, but the abstract does not state that EWAD+CPDP performs per-sample (or explicit) reliability gating/selection; it describes entropy-weighted adaptive distillation plus a capacity-proportional geometric constraint from a second teacher. Framing EWAD+CPDP as using the same reliability-decision mechanism as CHAD is not supported by the abstract.

In low-resource summarization, vanilla knowledge distillation often harms learning; reliability-aware distillation helps by trusting the teacher only when it’s useful.

Shows KD is not uniformly beneficial per example (many samples push the student the wrong way) and proposes two reliability-aware strategies to downweight harmful teacher signals; validates that gains vary by language. CHAD estimates whether KD gradients help validation loss and trains a gating model to predict helpful vs. harmful samples; EWAD+CPDP adaptively weights KD by token entropy and adds a capacity-proportional constraint using a second, vocab-incompatible teacher to add complementary signal. On BanSum (Bangla), standard KD is essentially zero gain over CE (+0.0003 ROUGE-L) and ~51.3% of samples are estimated harmful; CHAD and EWAD+CPDP improve ROUGE-L over standard KD by +0.0173 and +0.0219, with a 60M student outperforming a fine-tuned Qwen2.5-3B; across 15 XL-Sum languages, EWAD+CPDP beats CE in 10/15 (not universal).

CultureTalk-ID: A Multi-Task Dialogue Benchmark for Cultural Commonsense in Indonesian Local Languages [arxiv]

Muhammad Dehan Al Kautsar, Salsabila Pranida, Bilal Elbouardi, Fajri Koto

CultureTalk-ID evaluates cultural commonsense where it actually appears—multi-turn dialogue—across Indonesian and 10 local languages.

Introduces the first dialogue-based cultural commonsense benchmark spanning 11 Indonesian/local languages, with 4,496 culturally grounded dialogues over 13 topics and three tasks covering reasoning, transfer, and culturally appropriate generation. Human-curated, native-speaker pipeline to create authentic culturally situated dialogues; tasks include dialogue-based MC cultural reasoning, culturally faithful MT, and language-steering generation/continuation in the intended variety while staying culturally appropriate. Delivers a new 11-language, dialogue-centric benchmark designed to expose cultural failure modes missed by prompt-only tests, via complementary tasks for understanding, cross-lingual transfer, and controlled culturally grounded generation.

QuantiBias: Benchmarking Quantization-Induced Bias in LLMs [arxiv]

Emilio Ferrara

Quantization can increase stereotyped generations in multilingual, open-ended settings while leaving standard refusal/MC safety metrics largely unchanged.

Identifies quantization-induced bias as a deployment risk and introduces QuantiBias to disentangle open-ended stereotype generation from control safety tasks (refusal, over-refusal, MC), attributing changes specifically to quantization. Evaluate the same model pre/post quantization with identical prompts across eight languages; measure refusals/over-refusals, MC unbiased choice, and open-ended stereotype generation; vary quantization families/levels and “reasoning before answer.” Across quantization ladders, models can still pass typical safety gates yet show higher stereotype generation in open-ended answers (~24–27% flagged by an independent judge across settings); compression monotonicity depends on judge, and adding reasoning can reduce bias for some quantizers but not others—so bias must be re-evaluated on the shipped quantized build.

MIRA-Ev:A Benchmark for Granular Evidence Detection and Relational Reasoning in Clinical Exams [arxiv]

Iker De la Iglesia, Johanna Ramirez-Romero, Jose Maria Villa-Gonzalez, Irune Urroz García, Ander Barrena, Aitziber Atutxa

MIRA-Ev benchmarks clinical reasoning by checking whether models can extract and relate the evidence behind answers, not just choose an option.

Creates a clinician-annotated argument-mining benchmark from Spanish MIR exam cases, capturing premises/claims and support/attack relations to expose evidence-use failures hidden by MCQA accuracy. Expert clinicians annotate span-level premises and claims plus directed support/attack links; released in Spanish, English, and Basque (including a first Basque clinical argumentation resource); evaluation is tiered: evidence sentence retrieval, component extraction, relation classification. Releases MIRA-Ev: multilingual (ES/EN/EU) MIR-based cases with expert span and relation annotations and a three-level task hierarchy for granular evidence detection and relational reasoning evaluation.

Multilingual Speech Processing

Transcription Policy as a Latent Variable: Activating Controllable Verbatim ASR with Word-Level Timing [\[arxiv\]](#)

Laurin Wagner, Mario Zusag, Bernhard Thallinger

ASR models implicitly learn a “verbatim vs. intended” transcription mode that skews WER and timestamps; simple control tokens can reliably switch modes, even cross-lingually.

Frames transcription policy as a latent variable learned from mixed supervision, explaining unstable decoding, misleading WER under policy mismatch, and broken word timing; makes the policy explicitly controllable and links it to better disfluency handling and timing. Train decoder control tokens on parallel intended/verbatim transcripts for the same audio, with a coverage-aware objective to force verbatim outputs to include disfluencies; add supervised cross-attention fine-tuning to improve word-level alignment/timestamps under disfluency. Policy mismatch can explain up to ~60% of apparent WER differences; control tokens reliably steer outputs and greatly improve disfluency recovery, including zero-shot transfer to German (disfluency F1 ~10%~79% from English-only supervision), and attention tuning improves word timestamps beyond forced alignment on disfluent speech.

DONDO: Open w2v-BERT Speech-Recognition Base Models for African Languages [\[arxiv\]](#)

Paul Azunre

DONDO releases Apache-2.0 w2v-BERT ASR base models for 27 African language varieties and shows how to get multilingual convenience with near-monolingual accuracy.

Provides openly licensed monolingual and multilingual ASR checkpoints plus a reproducible recipe to bootstrap from license-clear read speech; shows staged fine-tuning and lightweight language conditioning reduce the usual multilingual accuracy penalty. Fine-tune w2v-BERT 2.0 on read speech from religious texts; use two-stage (annealed learning-rate) multilingual fine-tuning to recover accuracy; condition language by prepending one-hot language-ID prefix frames to acoustic features. Annealed multilingual checkpoints reach ~10–13% average WER across model families, closing most of the multilingual–monolingual gap; all weights are released under Apache-2.0 on Hugging Face, enabling real reuse and commercial adaptation.

Field Overview

Today’s submissions are dominated by LLMs/agents and their reliability, with at least ~120 titles centered on agentic systems (memory, context management, tool use, multi-agent RAG, benchmarks like DocOps/GuardianAgentBench/ARBIGRAPH, and safety for long-horizon action). A second major cluster is efficiency/inference engineering for foundation models (roughly ~40 papers) covering KV-cache management/eviction/compression, speculative decoding, quantization and its side effects (bias, safety, routing), and edge/on-device runtimes. The most striking “surprising” concentration is audio/speech+LLMs: well over ~200 papers on ASR, speech LLMs, TTS, audio-language models, deepfake detection/watermarking, and streaming/full-duplex voice agents—far denser than typical daily mixes—suggesting a strong push toward production-grade voice interaction and provenance/security. Across these clusters, evaluation/benchmarking and auditing is unusually prominent (at least ~60 papers) spanning hallucination/citation trust, cultural/value alignment, bias, prompt sensitivity, and domain-specific reliability (finance, legal, medical), indicating a shift from capability demos toward measurement, governance, and deployment constraints.
